Generalized MLMs for Persons Crossed with Items (i.e., *Explanatory* Item Response Theory or Latent Trait Models)

Topics:

- MLM as an alternative to multiple types of ANOVAs
- > IRT models as "items as fixed effects" MLMs
- > Explanatory IRT models as "items as random effects" MLMs

Prelude: The Hofflin Lego-Based View of Quantitative Methods

Big Picture Idea:

If you understand the elemental building blocks of statistical models, then you can build **anything**!

I believe that thinking this way has shaped my teaching and research for the better!

The 4 Lego Building Blocks

- 1. Linear models (for answering questions of prediction)
- 2. **Estimation** (for iterative ways of **finding the answers**)

- 3. **Link functions** (for predicting **any type of outcome**)
- 4. (a) Random effects /
 - (b) Latent traits / factors / variables
 - (a) for modeling multivariate "correlation/dependency"
 - (b) for modeling relations of "unobserved constructs"

How the Blocks Fit Together

- Linear models answer research questions, and are the first building block of every more complex analysis
 - Is there an effect? Is this effect the same for everyone?
 Is the effect still there after considering something else?
 - This is why I drill linear models so much in my classes!

To add more blocks, we need iterative estimation

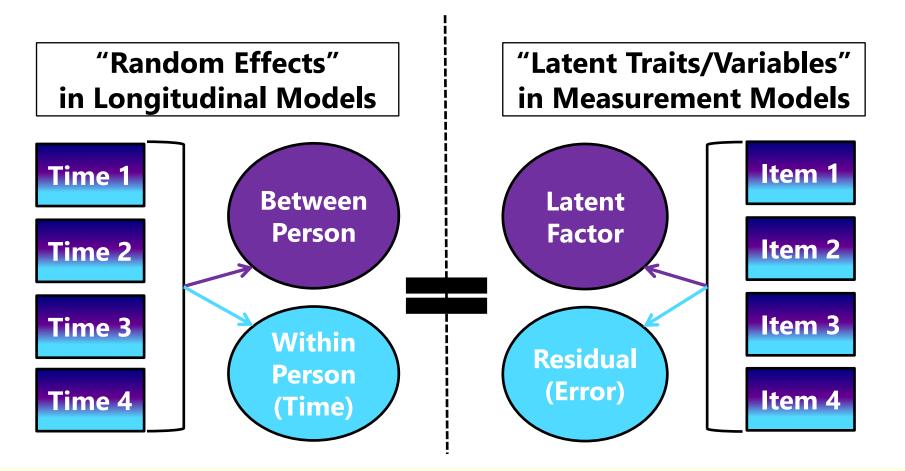

2. Maximum likelihood or Bayesian (e.g., MCMC)

What other blocks you will need is determined by:

- 3. How your outcome is measured \rightarrow link functions
- 4. Your dimensions of sampling → random/latent effects

From One to Many Outcomes...

- Most designs have more than one outcome per person...
 - > e.g., multiple outcomes, occasions, items, trials ... per person
 - > Multiple dimensions of **sampling** > multiple kinds of **variability**

4. Random Effects / Latent Variables

- Random effects are for "handling dependency" that arises because multiple dimensions of sampling → multiple variances
 - Occasions within children (need 1+ random effect)
 - Children within classrooms within schools (need 2+ random effects)
 - > aka, multilevel, mixed, or hierarchical linear models
- Latent <traits/factors/variables> are for representing "error-free true construct variance" within observed variables
 - Normal outcomes + latent variables = confirmatory FA (CFA; SEM)
 - Categorical outcomes + latent variables = item response theory (IRT)
- Random effects / latent variables are mechanisms by which:
 - > Make best use of all the data; avoid list-wise deletion of incomplete data

Quantify and predict distinct sources of variation... cue story-time...

The Curse of Non-Exchangeable Items

Jim Bovaird, University of Nebraska-Lincoln

Larry Locker, Georgia Southern University

- Psycholinguistic research (items are words and non-words)
 - Common persons, common items designs
 - Contentious fights with reviewers about adequacy of experimental control when using real words as stimuli
 - Long history of debate as to how data should be analyzed: F1 ANOVA, F2 ANOVA, or both?

Larry's Kinds of ANOVAs

Original Data per Person

| | B1 | B2 | | |
|----|--------------------------------------|--------------------------------------|--|--|
| A1 | Item 001 Item 002 Item 100 | Item 101 Item 102 Item 200 | | |
| A2 | Item 201 Item 202 Item 300 | Item 301 Item 302 Item 400 | | |

Person Summary Data

| | B1 B2 | | | |
|----|------------------|------------------|--|--|
| A1 | Mean (A1, B1) | Mean (A1, B2) | | |
| A2 | Mean (A2, B1) | Mean (A2, B2) | | |

"F1" Within-Persons ANOVA on N persons:

$$RT_{cp} = \gamma_0 + \gamma_1 A_c + \gamma_2 B_c + \gamma_3 A_c B_c + \mathbf{U_{0p}} + e_{cp}$$

"F2" Between-Items ANOVA on I items:

$$RT_i = \gamma_0 + \gamma_1 A_i + \gamma_2 B_i + \gamma_3 A_i B_i + e_i$$

Item Summary Data

| | B1 |
|--------|--|
| A1, B1 | Item 001 = Mean(Person 1, Person 2, Person N) Item 002 = Mean(Person 1, Person 2, Person N) Item 100 |
| A1, B2 | Item 101 = Mean(Person 1, Person 2, Person N) Item 102 = Mean(Person 1, Person 2, Person N) Item 200 |
| A2, B1 | Item 201 = Mean(Person 1, Person 2, Person N) Item 202 = Mean(Person 1, Person 2, Person N) Item 300 |
| A2, B2 | Item 301 = Mean(Person 1, Person 2, Person <i>N</i>) Item 302 = Mean(Person 1, Person 2, Person <i>N</i>) Item 400 |

Multilevel Models: A New Way of Life?

Original Data per Person

| | B1 | B2 | |
|----------|----------------------|----------------------|--|
| A1 | Item 001 Item 002 | Item 101 Item 102 | |
| | Item 100 | Item 200 | |
| Α2 | Item 201 Item 202 | Item 301 Item 302 | |
| <i>,</i> | Item 300 | Item 400 | |

Pros:

- Use all original data, not summaries
- Responses can be missing at random
- Can include continuous predictors

Cons:

Is still wrong (is ~F1 ANOVA)

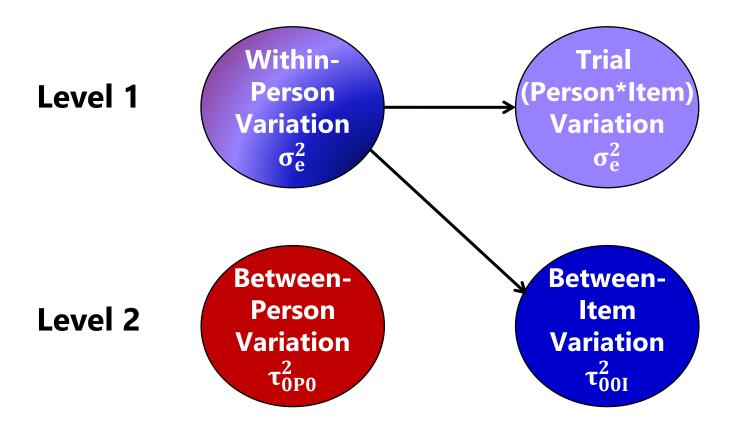

Level 1:
$$y_{ip} = \beta_{0p} + \beta_{1p}A_{ip} + \beta_{2p}B_{ip} + \beta_{3p}A_{ip}B_{ip} + e_{ip}$$

Level 2:
$$\beta_{0p} = \gamma_{00} + U_{0p}$$

 $\beta_{1p} = \gamma_{10}$
 $\beta_{2p} = \gamma_{20}$
 $\beta_{3p} = \gamma_{30}$

Level 2 = Between-Person Variation

Multilevel Models: A New Way of Life?

A Better Way of (Multilevel) Life

 $\begin{array}{c} \text{Between-} \\ \text{Person} \\ \text{Variation} \\ \text{L2 } \tau_{0P0}^2 \end{array}$

Between-ltem Variation L2 τ_{00I}^2

Trial (Person*Item) Variation $L1 \sigma_e^2$

Random effects over **persons** of **item** or **trial** predictors can also be tested and predicted.

Multilevel Model with Crossed Random Effects:

```
\begin{split} RT_{tpi} &= \gamma_{000} + \gamma_{001}A_i + \gamma_{002}B_i + \gamma_{003}A_iB_i \\ &+ \textbf{U}_{0p0} + \textbf{U}_{00i} + \textbf{e}_{tpi} \end{split}
```

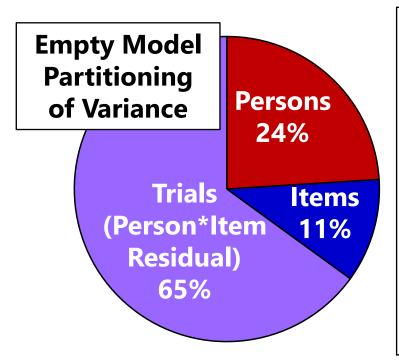

t trial
p person
i item

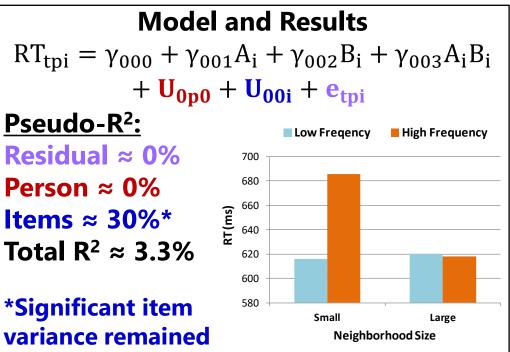

- Explicitly test persons and items as random effects:
 - \succ Person predictors capture between-person mean variation: τ_{0P0}^2
 - > Item predictors capture between-item mean variation: τ_{00I}^2
 - \gt Trial predictors capture trial-specific residual variation: σ_e^2

Larry's Data: See bonus posted on 10/24

- Crossed design: 38 persons by 39 items (words or nonwords)
- Lexical decision task: Response Time to decide if word or nonword
- 2 word-specific predictors of interest:
 - > A: Low/High Phonological Neighborhood Frequency
 - B: Small/Large Semantic Neighborhood Size

*F2 ANOVA was closest to MLM results

Not Just in Larry's Example Data...

- Generality of results examined via simulation study of Type I error rates for person or item predictor effects
 - > As reported in Hoffman, 2015, chapter 12
- Testing person effects in common persons design?
 - Need person variance to exist in model (so not F2 ANOVA)
 - Need random effect for persons (in MLM or in F1 ANOVA), so that person predictors can explain that person variance
- Testing item effects in common items design?
 - Need item variance to exist in model (so not F1 ANOVA)
 - Need random effect for items (in MLM or in F2 ANOVA), so that item predictors can explain that item variance

Nested vs. Crossed Items in Multilevel Designs

- When should items be a separate level-2 random effect?
 - Items are clearly nested within persons if the model fixed effects
 explain ALL of the item variation (so no item variation remains)
 - e.g., via item-specific indicators (CFA, IRT; stay tuned)
 - e.g., by item design features given only one item per condition
 - > Items are clearly nested within persons if they are **endogenous**
 - e.g., autobiographical memories, eye movements, speech utterances
 - > More ambiguous if items are **randomly generated** per person
 - If items are truly unique per person, then there are no common items... but items are usually constructed systematically
 - Modeling items as nested (no variance) assumes exchangeability
- When does this matter? When turning experimental tasks into instruments in which the outcome is nonnormal, and we want to predict sources of item difficulty

Latent Variables = Random Effects

• 1PL model predicts accuracy via fixed item effects and random person effects (i.e., n items are nested in persons)

"Rasch" version of 1PL model:

- > Probability $(y_{pi} = 1 | \theta_p) = \frac{\exp(\theta_p b_i)}{1 + \exp(\theta_p b_i)}$
- > Logit $(y_{pi} = 1 | \theta_p) = \theta_p b_i$

b_i is fixed effect of difficulty per item

 θ_p is random person ability (estimated variance τ_{θ}^2)

• 1PL is also a generalized multilevel model (t = trial):

> Logit(
$$y_{tpi} = 1 | U_{0p0}) = \gamma_{001}I_1 + \gamma_{002}I_2 + \cdots + \gamma_{00n}I_n + U_{0p0}$$

Because item difficulty/easiness is perfectly predicted by the *I* indicator variables, here items do not need a level-2 crossed random effect γ_{00i} is fixed effect of easiness per item

 U_{0p0} is random person ability (estimated variance τ_{0P0}^2)

Latent Variables = Random Effects

1PL model identification:

- > Logit $(y_{pi} = 1 | \theta_p) = \theta_p b_i$
- > On means side, fix one of these to 0:
- **b_i** is fixed effect of difficulty per item
- θ_p is random person ability (variance τ_{θ}^2)
- One item difficulty, sum of item difficulties, or theta mean
- > One variance side, fix one of these to 1:
 - Item discrimination ("Rasch" version) or theta variance ("1PL" version)

γ_{00i} is fixed effect of easiness per item

 U_{p0} is random person ability (variance τ_{0p0}^2)

1PL as Generalized MLM:

- > Logit($y_{tpi} = 1 | \mathbf{U_{0p0}}) = \gamma_{001} \mathbf{I_1} + \gamma_{002} \mathbf{I_2} + \dots + \gamma_{00n} \mathbf{I_n} + \mathbf{U_{0p0}}$
- Will be on the same scale as 1PL model when theta mean = 0 and item discrimination is fixed to 1 so that person random intercept variance is estimated ("Rasch version")

Adding Lego #1: Linear Models

- 1PL can be extended to **predict item difficulty** via the LLTM ("linear logistic test model" by Fisher in 1970s and 1980s)
- **LLTM** $\rightarrow k$ item features predict b_i ; random persons (θ_p) :
 - > Logit $(y_{pi} = 1 | \theta_p) = \theta_p b_i$
 - $\label{eq:bi} \triangleright \ b_i = \gamma_0 + \gamma_1 X_{1i} + \gamma_2 X_{2i} + \dots + \gamma_k X_{ki}$

Item difficulty = linear model of k item features (of X* γ fixed effects); θ_p is random person ability (variance τ_{θ}^2)

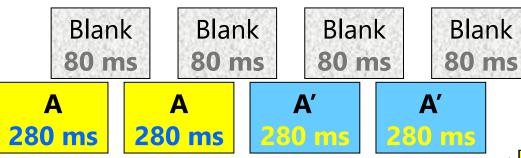

· LLTM written as a generalized multilevel model:

$$\text{Logit}(y_{tpi} = 1 | \mathbf{U_{p0}}) = \gamma_{000} + \gamma_{001} \mathbf{X_{1i}} + \gamma_{002} \mathbf{X_{2i}} + \dots + \gamma_{00k} \mathbf{X_{ki}} + \mathbf{U_{0p0}}$$

Because there is no random item effect, the model says that items are still just nested within persons—that item difficulty or easiness is *perfectly* predicted by the *X* item features (no item differences remain)

Item easiness = a linear model of k item features (of X* γ fixed effects); U_{0p0} is random person ability (variance τ_{0p0}^2)

Example: Measuring Visual Search Ability

cycle continues until response for max of 45 sec

Rated Item Design Features:

- Visual clutter of the scene
- Relevance of the change to driving
- Brightness of the change
- Change made to legible sign
- 155 persons, 36 items retained,
 DV = accuracy (for now)

Change detection task using the "flicker paradigm"

Proof of Concept: Random Items Matters

Item re-analysis predicting accuracy in dissertation data using SAS PROC GLIMMIX (Laplace estimation)

| Effect | Items Treated as Fixed | | Items Treated as Random | | | |
|--------------|------------------------|-------|-------------------------|--------|-------|-------|
| | Est | SE | p < | Est | SE | p < |
| Intercept | 1.082 | 0.072 | .0001 | 1.348 | 0.260 | .0001 |
| Clutter | -0.268 | 0.055 | .0001 | -0.324 | 0.242 | .1809 |
| Relevant | 0.220 | 0.099 | .0266 | 0.037 | 0.426 | .9306 |
| Brightness | 0.474 | 0.113 | .0001 | 0.790 | 0.499 | .1136 |
| Legible Sign | 0.662 | 0.082 | .0001 | 0.739 | 0.337 | .0283 |
| | | | | | | |

- Btw, the explanatory IRT models considered here do not have item-specific discrimination (= slope of prediction by trait)
- Item differences in discrimination can be modeled using fixed effects (i.e., a "2PL model" or separate factor loadings) or using random effects → variance in discrimination could be predicted!

Putting It All Together...

 Experimental tasks can become psychometric instruments via explanatory IRT (generalized multilevel) models in which items and persons have crossed random effects at level 2

$$Logit(y_{tpi} = 1) = \gamma_{000} + \gamma_{001}X_{1i} + \gamma_{002}X_{2i} + \dots + \mathbf{U_{0p0}} + \mathbf{U_{00i}}$$

- $ightharpoonup U_{0p0}$ is person ability with random (unpredicted) variance of au_{0p0}^2
- \mathbf{V}_{00i} is item easiness is predicted from a linear model of the X item features, with random (leftover) variance of $\mathbf{\tau}_{00i}^2$
- \gt Can add person predictors to explain τ_{0P0}^2
- Can examine random effects across persons of X item features (i.e., differential susceptibility to item manipulations)

Let's try to estimate these models using SAS, STATA, and R!
